

- Are units documented that were used for measurements?
- Are acceptable ranges of variables documented? If yes, do all variables contain plausible value ranges (measured with the same units)?
- Was the data checked (by you or someone else) for internal implausibilities/ relational contradictions? If yes, is the data free of internal implausibilities/relational contradictions?
- Are date and time format consistent and valid?
- Are there any implausible sequences (e.g. discharge before admission)?
- Was the data checked (by you or someone else) for implausibilities regarding external knowledge? If yes, is the data free of implausibilities regarding external knowledge?
- Can people involved in measurements and processing of the data be reached to confirm extreme outliers or unusual values?
- Did humans interacting with the data have high expertise?
- Do all frequencies match known epidemiological patterns? (E.g. Is the prevalence of diabetes, hypertension, etc., within expected national or regional ranges)
- Were the labels/annotations assigned using the medical gold standard? (E.g. diagnostic test)
- Were the labels/annotations derived by humans?
- Was the data labeled by multiple raters?
- Does the dataset contain variables with interdependencies?
- Is all metadata correctly linked to other datatypes? (E.g., are mammograms associated only with female patients of appropriate age?
- Does the dataset contain any sources of errors or noise?
